Background
Inhalation of hydrogen (H2) has been demonstrated to mitigate post-resuscitation (PR) neurological injuries in rat studies. However, before application in clinical settings, the efficacy of H2 needs to be verified in larger animals that have a physiology and pathophysiology similar to human beings. In the present study, we investigated the effects of treatments with H2 on post resuscitation (PR) neurological function in a porcine model of prolonged cardiac arrest (CA). We hypothesize that Inhalation of H2 improves neurological injuries after resuscitation in a CA porcine model.

Methods
Twenty male domestic pigs weighing 38 ± 3 kg were utilized. Ventricular fibrillation (VF) was induced electrically and CPR was initiated after 10 mins of untreated VF. All the animals were resuscitated successfully and randomized into two groups immediately following resuscitation: Inhalation of H2 (H group, N=10) or inhalation of room air (C group, N=10). Animals in the H group were ventilated with 2% H2/21% oxygen from PR 5 min to PR 2 h. Serum levels of S100B and neuron-specific enolase (NSE) were measured by ELISA at baseline and PR 360 min. The neurological deficit score (NDS) was evaluated daily for a total of 72 hours.

Values are presented as mean ± SD. NDS, neurological deficit score: C group, control group; H group, two hours delayed inhalation of H2 group. * p < .05 vs. the C group

Figure: Kaplan-Meier analysis of cumulative survival

A better NDS at 24h, 48h and 72h was observed in the H group compared with the C group (Table). The serum levels of S100B and NSE were lower in the H group when compared with the C group (Figure).

Conclusions
Inhalation of H2 improves neurological injuries after resuscitation in a prolonged CA porcine model.
